Project Description

Traumatic Brain Injury (TBI) leads to nearly 3 million emergency department visits annually in the United States alone. The generation of neuropsychiatric disorders following TBI is common and the molecular mechanisms driving these effects are currently not well understood. Utilizing a preclinical model for TBI, we have discovered alterations in specific aspects of serotonin (5-HT) signaling following injury that are correlated to changes in behavior. We hypothesize that these changes are driving changes in behavior that are associated with disrupted social function and/or the generation of depression. The current WISE project therefore focuses on whether pharmacologically targeting 5-HT2A receptors reverses TBI-induced deficits in social behavior and/or increased despair-like behavior. The WISE student will be tasked with conducting experiments, utilizing a murine model of blast-induced TBI, to study the role of 5-HT2A receptors in the behavioral and biochemical ramifications of neural injury. The WISE student will learn various assays relevant to the study of rodent behavior and will be exposed to a wide breadth of standard molecular biology techniques such as real-time quantitative PCR, western blotting, and ELISA assays. Additionally, the student will receive training in the areas of data analysis and the presentation of scientific data. All research will be conducted under the approved IACUC protocol #18-01-17-01.
